Internet Protocols EBU5403 The Network Layer Part I

Michael Chai (michael.chai@qmul.ac.uk)
Richard Clegg (r.clegg@qmul.ac.uk)
Adnan Kiani (adnankhal@googlemail.com)

	Week I	Week 2 Week 3		Week 4		
Telecom	Adnan Kiani	Michael Chai				
E-Commerce	Richard Clegg	Michael Chai Richard Clegg				

Structure of course

Highlight where we are

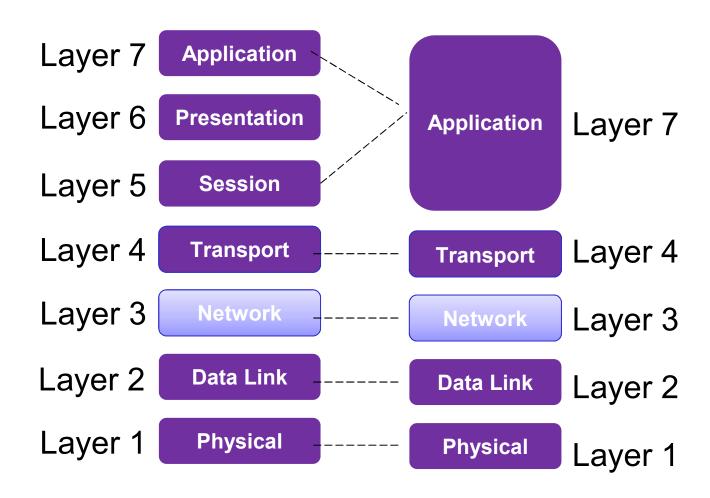

- Week I (25th-29th September)
 - Introduction to IP Networks
 - The Transport layer (part 1)
- Week 2 (16th-21st October)
 - The Transport layer (part II)
 - The Network layer (part I)
 - Class test (open book exam in class)
- Week 3 (20th-24th November)
 - The Network layer (part II)
 - The Data link layer (part I)
 - Router lab tutorial (assessed labwork after this week)
- Week 4 (18th-22nd December)
 - The Data link layer (part II)
 - Security and network management
 - Class test

Network Layer: outline

- 4.1 Overview of Network layer
 - data plane
 - control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - network address translation
 - IPv6

- 4.4 Generalized Forward and SDN
 - match
 - action
 - OpenFlow examples of match-plus-action in action

Network Layer

Network layer

Goals:

- understand principles behind network layer services, focusing on data plane:
 - network layer service models
 - forwarding versus routing
 - how a router works
 - generalized forwarding
- instantiation, implementation in the Internet

Two key network-layer functions

network-layer functions:

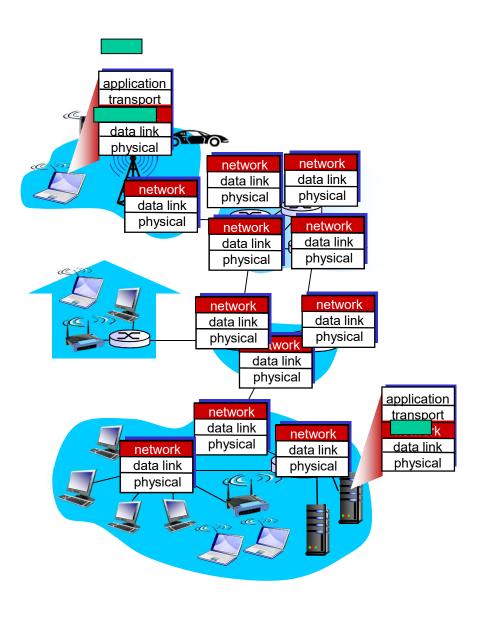

- •forwarding: move packets from router's input to appropriate router output
- •routing: determine route taken by packets from source to destination
 - routing algorithms

analogy: taking a trip

- forwarding: process of getting through one road junction
- routing: process of planning trip from source to destination

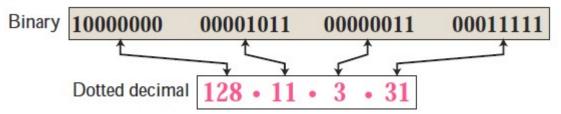

Network layer

- transport segment from sending to receiving host
- on sending side encapsulates segments into datagrams
- on receiving side, delivers segments to transport layer
- network layer protocols in every host, router
- router examines header fields in all IP datagrams passing through it

IPv4 address notation

- There are three common notations to show an IPv4 address:
 - binary notation
 - dotted-decimal notation (most commonly used)
 - hexadecimal notation

Exercise: convert the following IPv4 addresses from binary to dotted-decimal notation.

- a. 10000001 00001011 00001011 11101111
- b. 11000001 10000011 00011011 11111111

Converting binary to/from decimal (8 bits)

Convert 10100010 to decimal

Factor	128	64	32	16	8	4	2	
Binary	1	0	1	0	0	0	I	0
Decimal	128	0	32	0	0	0	2	0

Add together 128 + 32 + 2 = 162

Convert decimal to binary – if number is bigger than or equal to factor subtract factor and put 1 in binary column. Example 155

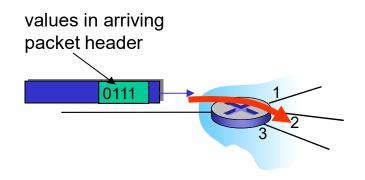

Factor	128	64	32	16	8	4	2	I
Decimal	155-128	27	27	27-16	11-8	3	3-2	1
Binary	1	0	0	1	1	0	1	1

155 in decimal is 10011011

Network layer: data plane, control plane

Data plane

- local, per-router function
- determines how datagram arriving on router input port is forwarded to router output port
- forwarding function

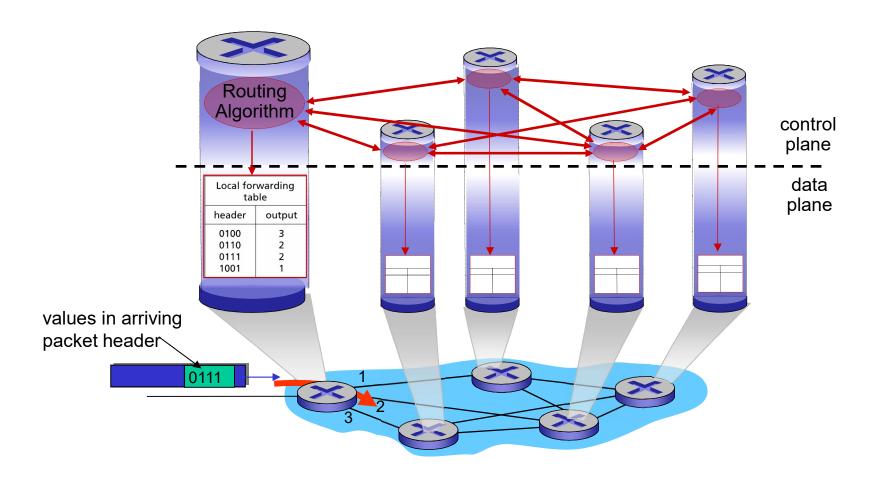

Control plane

- network-wide logic
- determines how datagram is routed among routers along end-end path from source host to destination host
- two control-plane approaches:
 - traditional routing algorithms: implemented in routers
 - software-defined networking (SDN): implemented in (remote) servers

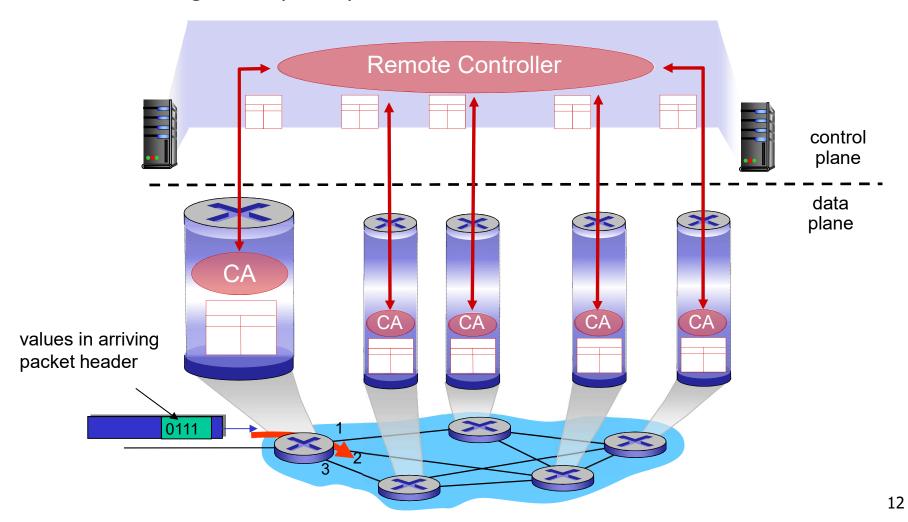

Per-router control plane

Individual routing algorithm components in each and every router interact in the control plane

Logically centralized control plane

A distinct (typically remote) controller interacts with local control agents (CAs)

Network service model

Q: What is service model for "channel" transporting datagrams from sender to receiver?

example services for individual datagrams:

- guaranteed delivery
- guaranteed delivery with less than 40 msec delay

example services for a flow of datagrams:

- in-order datagram delivery
- guaranteed minimum bandwidth to flow
- restrictions on changes in inter-packet spacing

Network layer service models:

Network		Service Model		Congestion			
Architecture	Bandwidth		Loss	Order	Timing	feedback	
	Internet	best effort	none	no	no	no	no (inferred via loss)
•	ATM	CBR	constant	yes	yes	yes	no
			rate				congestion
	ATM	VBR	guaranteed	yes	yes	yes	no
			rate				congestion
•	ATM	ABR	guaranteed	no	yes	no	yes
			minimum				
	ATM	UBR	none	no	yes	no	no

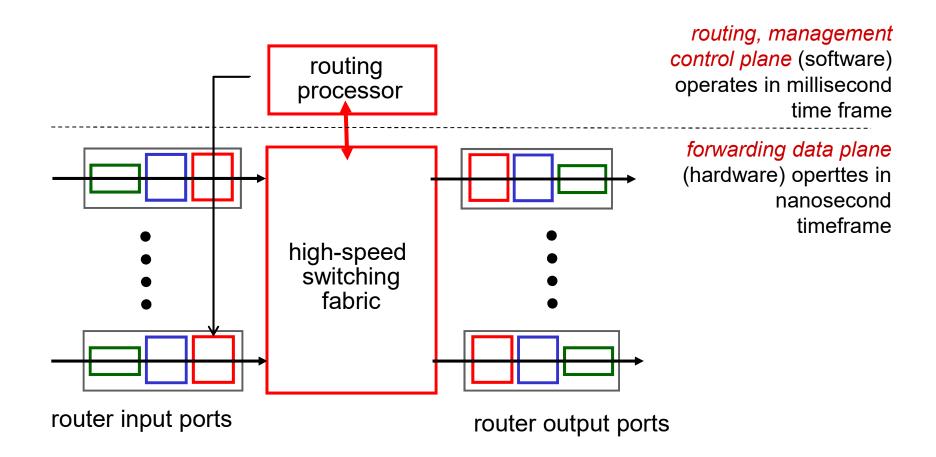

Network Layer (Data): outline

- 4.1 Overview of Network layer
 - data plane
 - control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - network address translation
 - IPv6

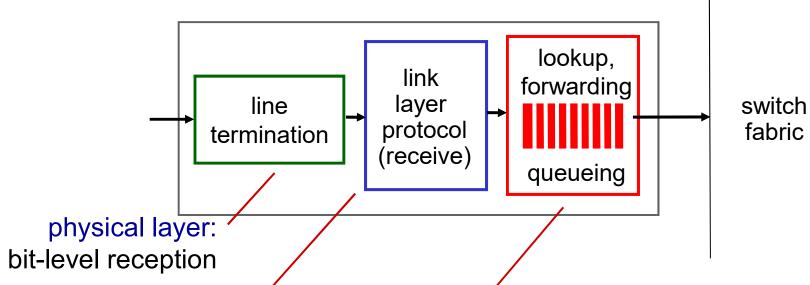

- 4.4 Generalized Forward and SDN
 - match
 - action
 - OpenFlow examples of match-plus-action in action

Router architecture overview

high-level view of generic router architecture:

Input port functions

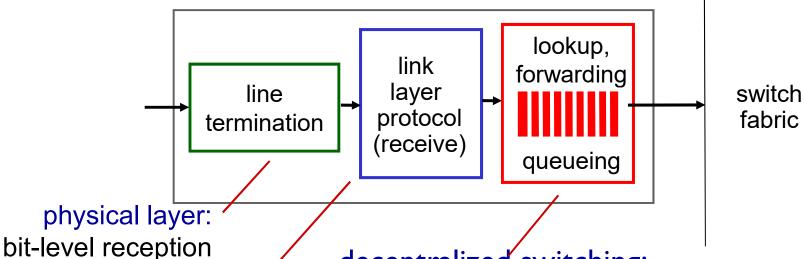

data link layer:

e.g., Ethernet see chapter 5 of course text

decentralizéd switching:

- using header field values, lookup output port using forwarding table in input port memory ("match plus action")
- goal: complete input port processing at 'line speed'
- queuing: if datagrams arrive faster than forwarding rate into switch fabric

Input port functions

data link layer:

e.g., Ethernet see next lectures

decentralized switching:

- using header field values, lookup output port using forwarding table in input port memory ("match plus action")
- destination-based forwarding: forward based only on destination IP address (traditional)
- generalized forwarding: forward based on any set of header field values

Destination-based forwarding

forwarding table						
Destination Address Range	Link Interface					
11001000 00010111 00010000 00000000 through 11001000 00010111 00010111 11111111	0					
11001000 00010111 00011000 00000000 through 11001000 00010111 00011000 11111111	1					
11001000 00010111 00011001 00000000 through 11001000 00010111 00011111 11111111	2					
otherwise	3					

Q: but what happens if ranges do not divide up so nicely?

Longest prefix matching

longest prefix matching

when looking for forwarding table entry for given destination address, use *longest* address prefix that matches destination address.

Destination	Link interface			
11001000	00010111	00010***	*****	0
11001000	00010111	00011000	*****	1
11001000	00010111	00011***	*****	2
otherwise				3

examples:

DA: 11001000 00010111 00010110 10100001

DA: 11001000 00010111 00011000 10101010

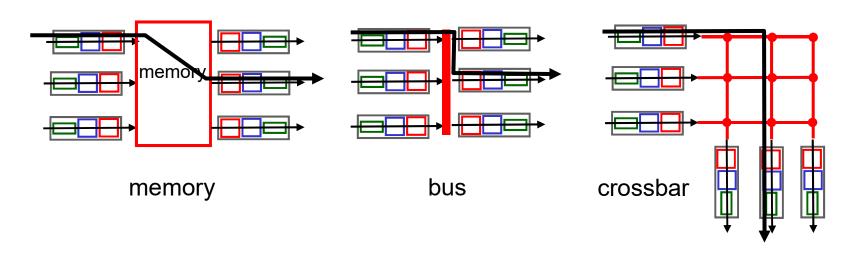

which interface? which interface?

Longest prefix matching

- we'll see why longest prefix matching is used shortly, when we study addressing
- longest prefix matching: often performed using ternary content addressable memories (TCAMs) specialised very high speed memory
 - content addressable: present address to TCAM: retrieve address in one clock cycle, regardless of table size
 - Cisco Catalyst: can up ~IM routing table entries in TCAM

Switching fabrics

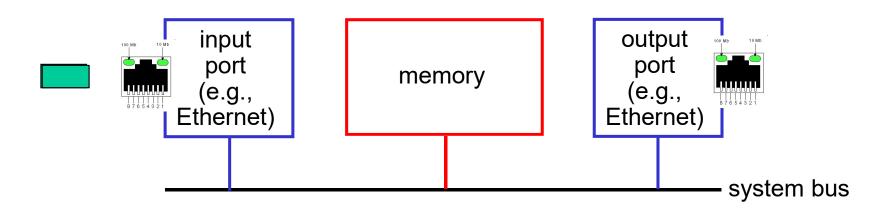

- transfer packet from input buffer to appropriate output buffer
- switching rate: rate at which packets can be transfer from inputs to outputs
 - often measured as multiple of input/output line rate
 - N inputs: switching rate N times line rate desirable
- three types of switching fabrics

Switching via memory

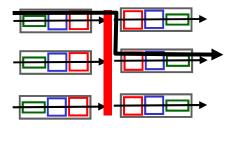

first generation routers:

- traditional computers with switching under direct control of CPU
- packet copied to system's memory
- speed limited by memory bandwidth (2 bus crossings per datagram)

Switching via a bus

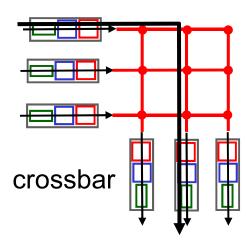

- datagram from input port memory to output port memory via a shared bus
- bus contention: switching speed limited by bus bandwidth
- 32 Gbps bus, Cisco 5600: sufficient speed for access and enterprise routers

bus

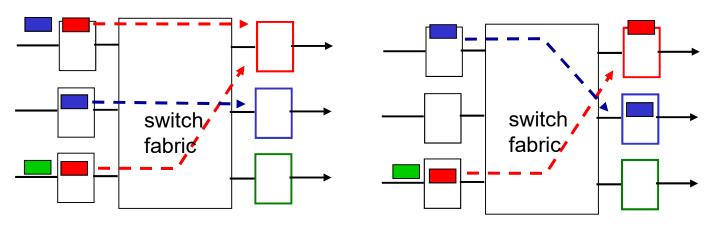

Switching via interconnection network

- overcome bus bandwidth limitations
- banyan networks, crossbar, other interconnection nets initially developed to connect processors in multiprocessor
- advanced design: fragmenting datagram into fixed length cells, switch cells through the fabric.
- Cisco I 2000: switches 60 Gbps through the interconnection network

Input port queuing

- fabric slower than input ports combined -> queueing may occur at input queues
 - queueing delay and loss due to input buffer overflow!
- Head-of-the-Line (HOL) blocking: queued datagram at front of queue prevents others in queue from moving forward

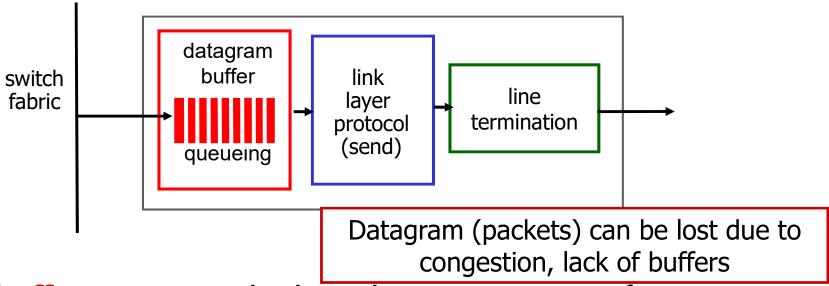

output port contention:
only one red datagram can be
transferred.
lower red packet is blocked

one packet time later:
green packet
experiences HOL
blocking

Output ports

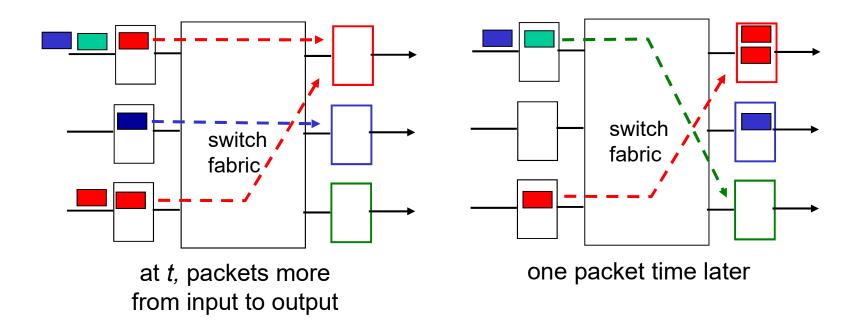

This slide is HUGELY important!

- buffering required when datagrams arrive from fabric faster than the transmission rate
- scheduling discipline chooses among queued datagrams for transmission

Priority scheduling – who gets best performance, network neutrality

Output port queueing

- buffering when arrival rate via switch exceeds output line speed
- queueing (delay) and loss due to output port buffer overflow!

How much buffering?

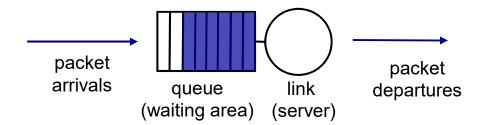

- RFC 3439 rule of thumb: average buffering equal to "typical" RTT (say 250 msec) times link capacity C
 - e.g., C = 10 Gpbs link: 2.5 Gbit buffer
- recent recommendation: with N flows, buffering equal to

$$\frac{\mathsf{RTT} \cdot \mathsf{C}}{\sqrt{\mathsf{N}}}$$

Why? Why not simply have very large buffers so no loss?

Scheduling mechanisms

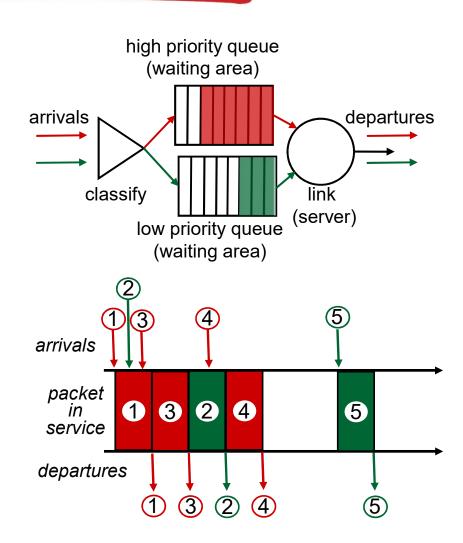

- scheduling: choose next packet to send on link
- FIFO (first in first out) scheduling: send in order of arrival to queue
 - real-world example?
 - discard policy: if packet arrives to full queue: who to discard?
 - tail drop: drop arriving packet
 - priority: drop/remove on priority basis
 - random: drop/remove randomly

Scheduling policies: priority

priority scheduling: send highest priority queued packet

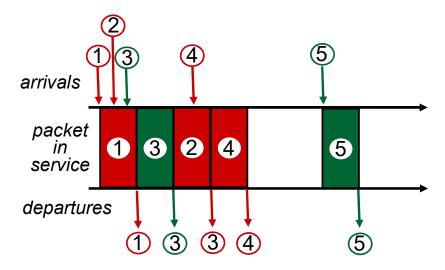

- multiple classes, with different priorities
 - class may depend on marking or other header info, e.g. IP source/dest, port numbers, etc.
 - real world example?

Scheduling policies: still more

Round Robin (RR) scheduling:

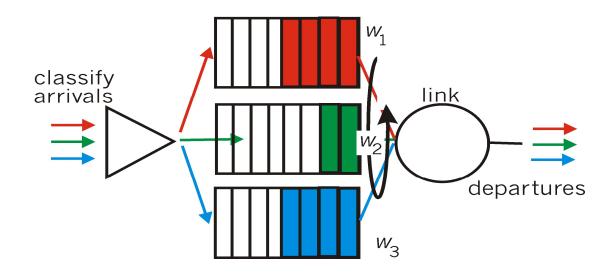

- multiple classes
- cyclically scan class queues, sending one complete packet from each class (if available)
- real world example?

Scheduling policies: still more

Weighted Fair Queuing (WFQ):

- generalized Round Robin
- each class gets weighted amount of service in each cycle
- real-world example?

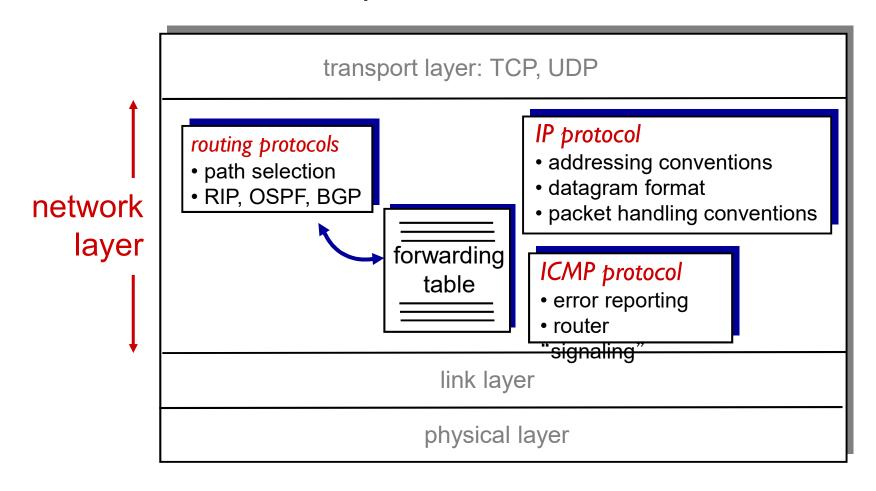

Network Layer: outline

- 4.1 Overview of Network layer
 - data plane
 - control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - network address translation
 - IPv6

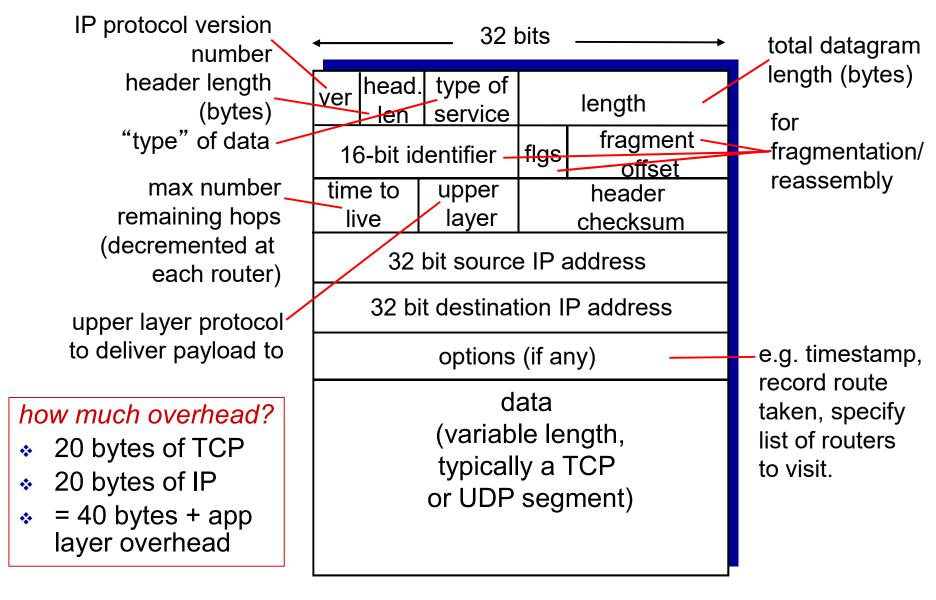

- 4.4 Generalized Forward and SDN
 - match
 - action
 - OpenFlow examples of match-plus-action in action

The Internet network layer

host, router network layer functions:

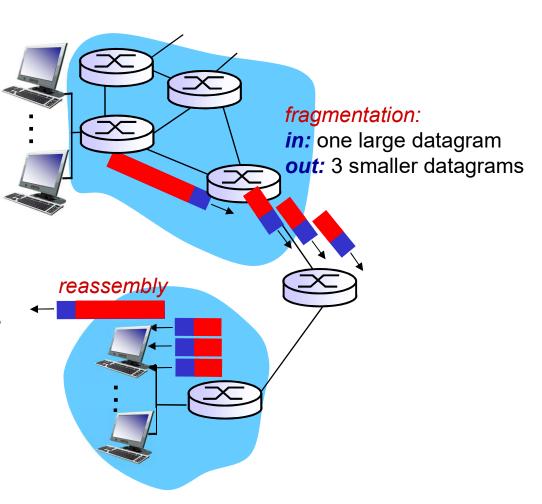

IP datagram format

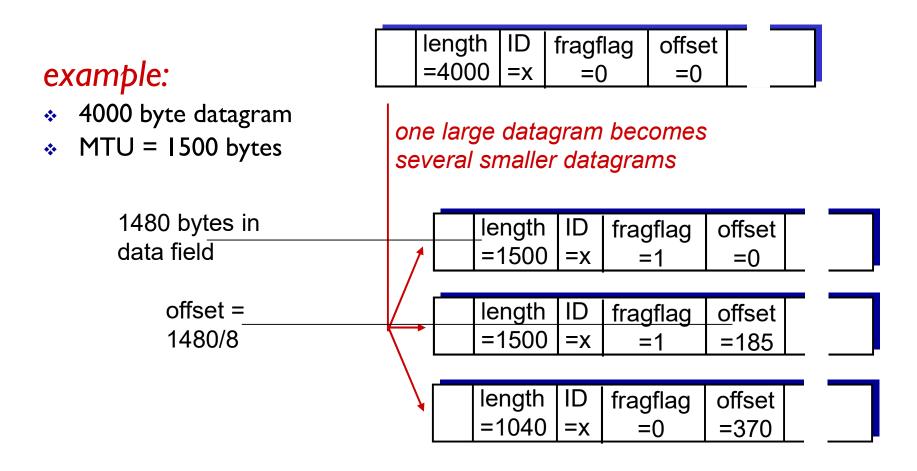

IP fragmentation, reassembly

- network links have MTU (max.transfer size) largest possible link-level frame
 - different link types, different MTUs
- large IP datagram divided ("fragmented") within net
 - one datagram becomes several datagrams
 - "reassembled" only at final destination
 - IP header bits used to identify, order related fragments

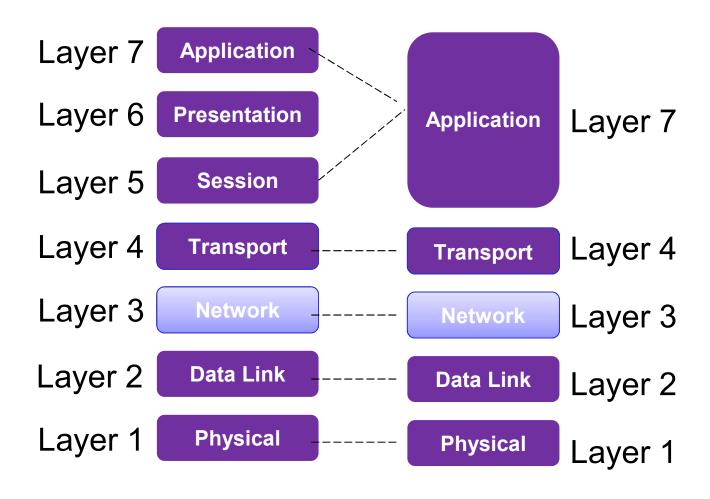

IP fragmentation, reassembly

What have we learned?

- Network layer moves data from "source" all the way to the "destination".
- Control plane makes decisions about routes taken by packets it spans a network.
- Data plane implements the decisions and gets the data from place to place. It is local to a router.
- Longest prefix matching on a router is used to pick where to send data.
- Queuing at routers can have huge effects.
- Scheduling polices can benefit some traffic over other traffic.
- Fragmentation and reassembly can be used to split and rejoin IP packets.

Network Layer

Network Layer (Data): outline

- 4.1 Overview of Network layer
 - data plane
 - control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - network address translation
 - IPv6

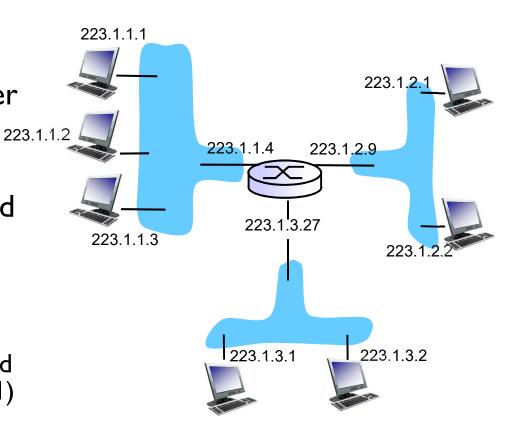

- 4.4 Generalized Forward and SDN
 - match
 - action
 - OpenFlow examples of match-plus-action in action

IP addressing: introduction

IP address: 32-bit identifier for host, router interface

 interface: connection between host/router and physical link

- routers typically have multiple interfaces
- host typically has one or two interfaces (e.g., wired Ethernet, wireless 802.11)
- IP addresses associated with each interface

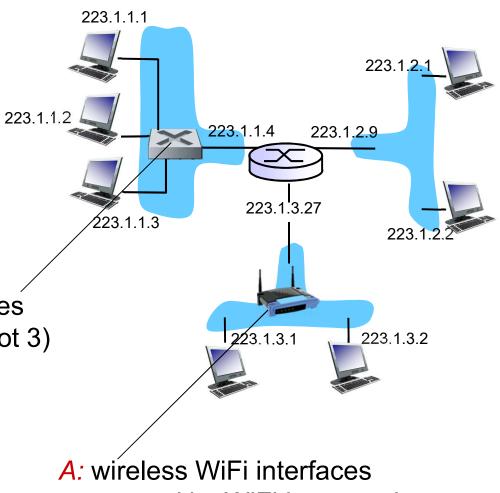

IP addressing: introduction

Q: how are interfaces actually connected?

A: we'll learn about that in later lectures.

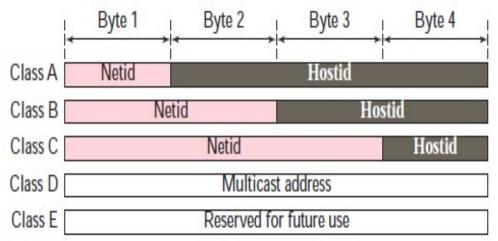

A: wired Ethernet interfaces connected by Ethernet switches (remember switches layer 2 not 3)

For now: don't need to worry about how one interface is connected to another (with no intervening router)

connected by WiFi base station

Classful IP addressing

- In classful addressing, the IP address space is divided into five classes: A, B, C, D, E.
- Starting number, n (first byte), shows whether Class A, B or C
 - **Class A**: n < 128 (up to 16m hosts)
 - Class B: $128 \le n < 192$ (up to 65K hosts)
 - Class C: $192 \le n < 224$ (up to 254 hosts)

	Octet 1	Octet 2	Octet 3	Octet 4	
Class A	0				
Class B	10				
Class C	110				
Class D	1110				
Class E	1111				
	Binary notation				

	Byte 1	Byte 2	Byte 3	Byte 4
Class A	0-127			
Class B	128-191			
Class C	192-223			
Class D	224-239			
Class E	240-255			

Dotted-decimal notation

Addresses for private networks

Class	Netids	Blocks
A	10.0.0	1
В	172.16 to 172.31	16
С	192.168.0 to 192.168.255	256

These addresses are "special" and not used on the general Internet. You use them to set up test networks or networks of machines not accessible from outside.

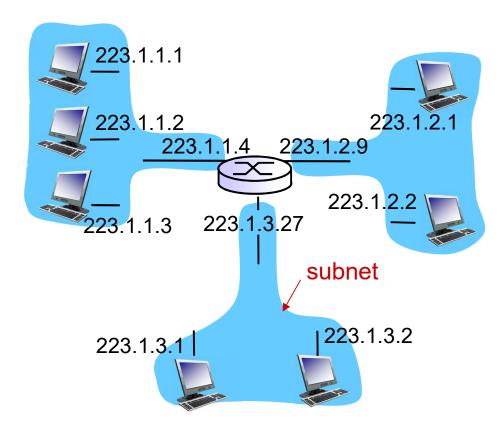

Subnets

■ IP address:

- subnet part high order bits
- host part low order bits

what 's a subnet ?

- device interfaces with same subnet part of IP address
- can physically reach each other without intervening router

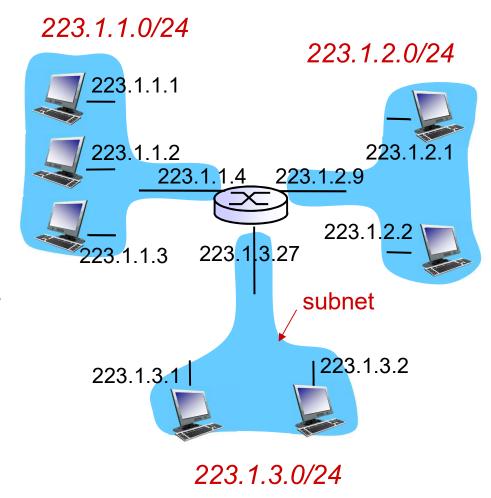

network consisting of 3 subnets

Subnets

recipe

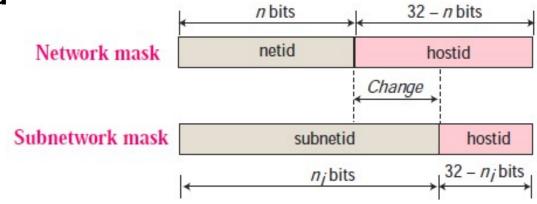

- to determine the subnets, detach each interface from its host or router, creating islands of isolated networks
- each isolated network is called a <u>subnet</u>
- subnet mask (or slash notation) number of bits taken to identify network
 - /8 size of old class A
 - /16 size of class B
 - /24 size of class C

subnet mask: /24

Network mask and subnetwork mask

Subnetting increases length of netid and decreases length of hostid

 To divide a network to s number of subnetworks, each of equal numbers of hosts, the subnetid for each subnetwork can be calculated as

$$n_{\text{sub}} = n + \log_2 s$$

n - length of netid, n_{sub} - length of each subnetid, s - number of subnets

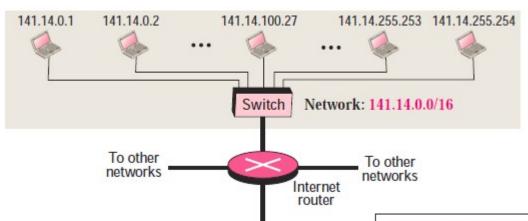

Three-Level Addressing: Subnetting

- The idea of splitting a block to smaller blocks is referred to as subnetting.
- In subnetting, a network is divided into several smaller subnetworks (subnets) with each subnetwork having its own subnetwork address.

Why subnetting?

- an organization that was granted a large block of IP addresses (a long time ago this would be class A, class B etc)
- wants to divide this into smaller blocks of addresses that are individual networks.
- Or perhaps organization wants to sell some of its IP addresses off.

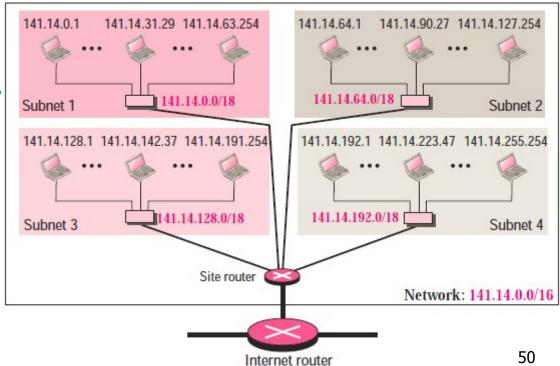

A subnetting example

To the rest of the Internet

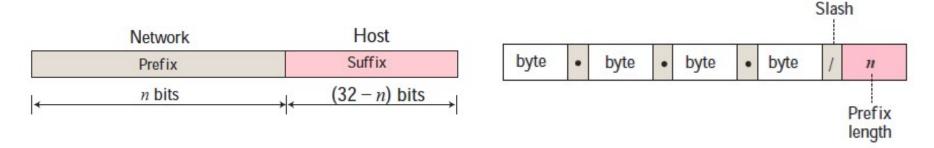

- A network using class B addresses before subnetting
- /16 to show the length of the netid (class B)

- a private site router is used to divide the network into four subnetworks.
- after subnetting, each subnetwork can now have almost 2¹⁴ hosts.
- /16 and /18 show the length of the netid and subnetids

Classless addressing

- In classless addressing, variable-length blocks are assigned that belong to no class.
- In this architecture, the entire address space (2³² addresses) is divided into blocks of different sizes.

 The slash notation is formally referred to as classless interdomain routing or CIDR (Classless InterDomain Routing) notation.

Subnets and / notation

Example I29.66.25.5/22 Host part 10 bits
 Network part (22 bits – because it is /22) (32 bits – 22 bits)
 10000001.01000010.00011001.00000101

Network address is the address with all the host bits set to zero – address like any other but represents the network. 10000001.01000010.00011000.0000000

Network address: 129.66.24.0/22

The network address is also the first usable IP address in the block

Broadcast address (sends to everyone) is the address with all the host bits set to one.

10000001.01000010.00011011.11111111

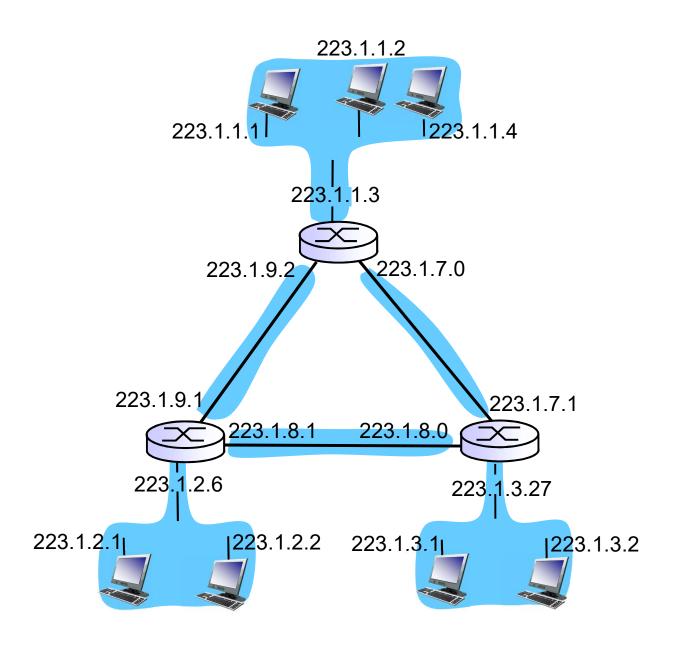

Broadcast address: 129.66.27.255/22

Splitting IP address by slash notation

- For a /n address, the first n bits are the network address and the last 32-n bits are for the host.
- If the host parts are all Is then this is the broadcast address – sent to all hosts on the network.
- Host has m = 32-n bits (e.g. /20 has m=12)
- Room for $2^m 1$ hosts (e.g. /20 has 4095)
- Example:
 - 140.120.84.24/20
 - Network address is 140.120.80.0/20
 - Broadcast address is 140.120.95.255/20
 - (95 is 01011111 255 is 11111111)
- /3 I only has I host address
- /30 is smallest subnet we can have 3 hosts
- /30 commonly used to connect just two routers (which must be on same subnet).

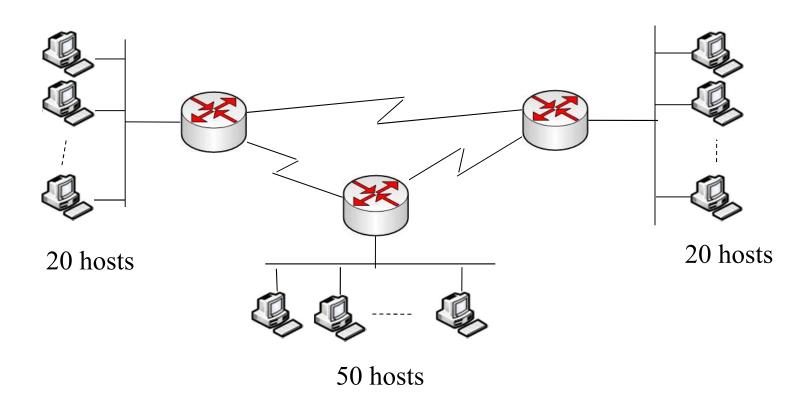

Subnets

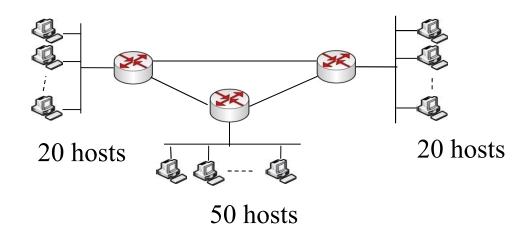

how many?

VLSM (variable length subnet mask)

Subnet 192.168.1.0/24 to address this network by using the most efficient addressing possible.

192.168.1.0/24

Network Data Plane: outline

- 4.1 Overview of Network layer
 - data plane
 - control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - network address translation
 - IPv6

- 4.4 Generalized Forward and SDN
 - match
 - action
 - OpenFlow examples of match-plus-action in action

IP addresses: how to get one?

Q: How does a host get IP address?

- hard-coded by system admin in a file
 - Windows: control-panel->network->configuration->tcp/ip->properties
 - UNIX: /etc/rc.config
- DHCP: Dynamic Host Configuration Protocol: dynamically get address from as server
 - "plug-and-play"

DHCP: Dynamic Host Configuration Protocol

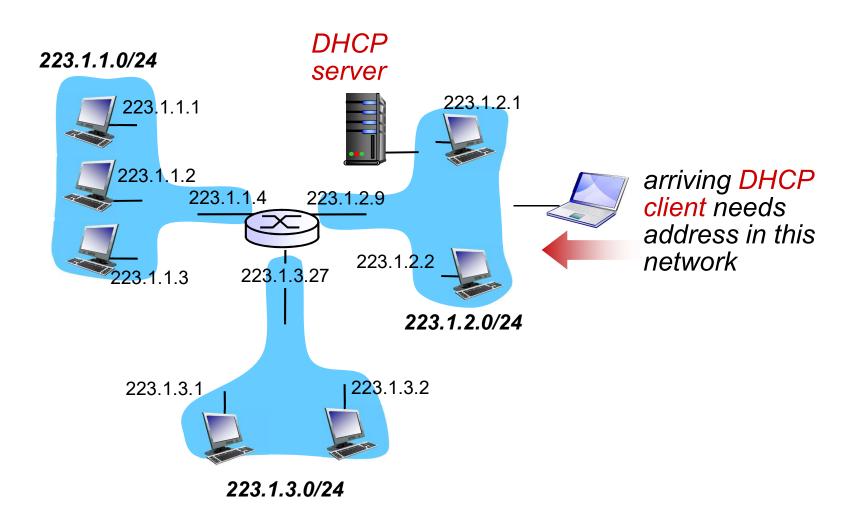

goal: allow host to dynamically obtain its IP address from network server when it joins network

- can renew its lease on address in use
- allows reuse of addresses (only hold address while connected/"on")
- support for mobile users who want to join network (more shortly)

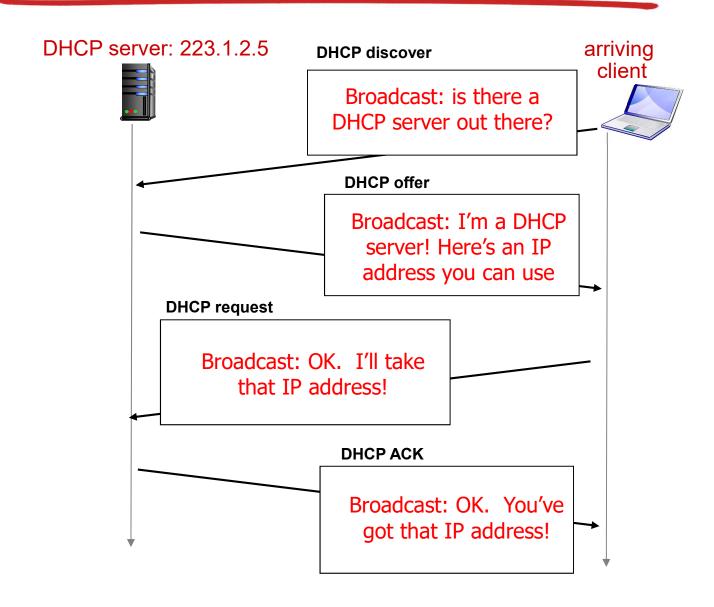

DHCP overview:

- host broadcasts "DHCP discover" msg [optional]
- DHCP server responds with "DHCP offer" msg [optional]
- host requests IP address: "DHCP request" msg
- DHCP server sends address: "DHCP ack" msg

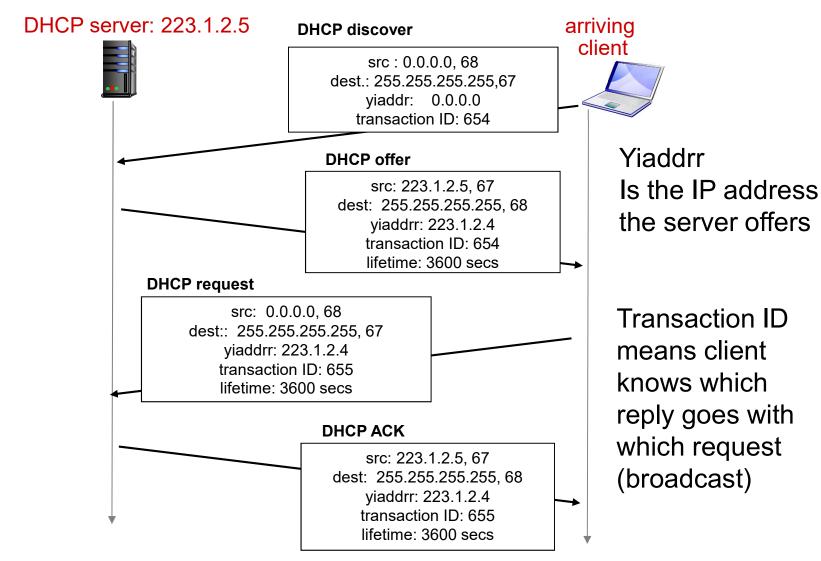

DHCP client-server scenario

DHCP client-server scenario

DHCP client-server scenario

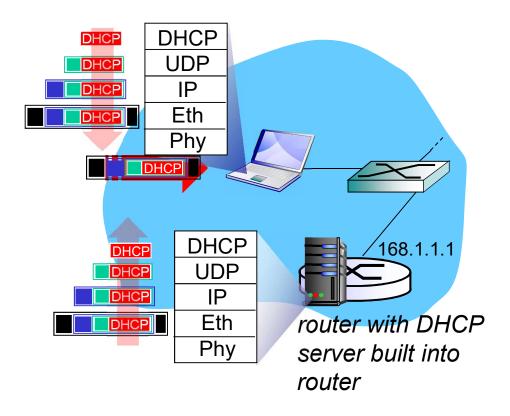

DHCP: more than IP addresses

DHCP can return more than just allocated IP address on subnet:

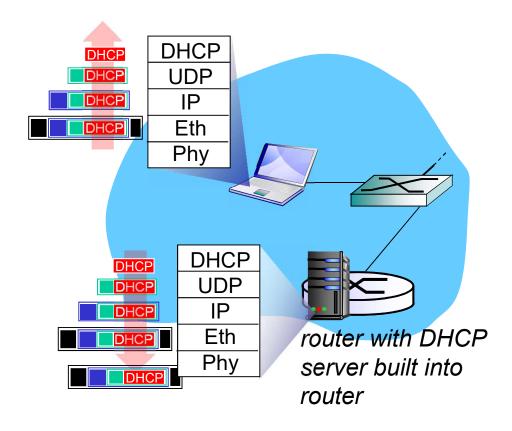

- address of first-hop router for client
- name and IP address of DNS sever
- network mask (indicating network versus host portion of address)

DHCP: example

- connecting laptop needs its IP address, addr of first-hop router, addr of DNS server: use DHCP
- DHCP request encapsulated in UDP, encapsulated in IP, encapsulated in 802.1 Ethernet
- Ethernet frame broadcast (dest: FFFFFFFFFFFFF) on LAN, received at router running DHCP server
- Ethernet demuxed to IP demuxed, UDP demuxed to DHCP

DHCP: example

- DCP server formulates DHCP ACK containing client's IP address, IP address of first-hop router for client, name & IP address of DNS server
- encapsulation of DHCP server, frame forwarded to client, demuxing up to DHCP at client
- client now knows its IP address, name and IP address of DNS server, IP address of its first-hop router

DHCP: Wireshark output (home LAN)

Message type: **Boot Request (1)** Hardware type: Ethernet Hardware address length: 6 request Hops: 0 Transaction ID: 0x6b3a11b7 Seconds elapsed: 0 Bootp flags: 0x0000 (Unicast) Client IP address: 0.0.0.0 (0.0.0.0) Your (client) IP address: 0.0.0.0 (0.0.0.0) Next server IP address: 0.0.0.0 (0.0.0.0) Relay agent IP address: 0.0.0.0 (0.0.0.0) Client MAC address: Wistron 23:68:8a (00:16:d3:23:68:8a) Server host name not given Boot file name not given Magic cookie: (OK) Option: (t=53,l=1) **DHCP Message Type = DHCP Request** Option: (61) Client identifier Length: 7; Value: 010016D323688A; Hardware type: Ethernet Client MAC address: Wistron 23:68:8a (00:16:d3:23:68:8a) Option: (t=50,l=4) Requested IP Address = 192.168.1.101 Option: (t=12,l=5) Host Name = "nomad" **Option: (55) Parameter Request List** Length: 11; Value: 010F03062C2E2F1F21F92B 1 = Subnet Mask; 15 = Domain Name 3 = Router: 6 = Domain Name Server 44 = NetBIOS over TCP/IP Name Server

```

IP addresses: how to get one?

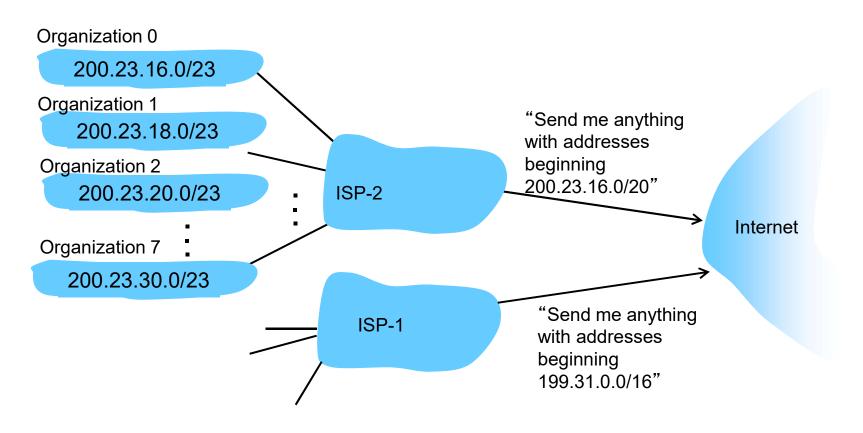

Q: how does network get subnet part of IP addr?

A: gets allocated portion of its provider ISP's address space

ISP's block	11001000	00010111	00010000	00000000	200.23.16.0/20
Organization 0 Organization 1					200.23.16.0/23 200.23.18.0/23
Organization 2	•				200.23.20.0/23
Organization 7	11001000	00010111	<u>0001111</u> 0	00000000	200.23.30.0/23

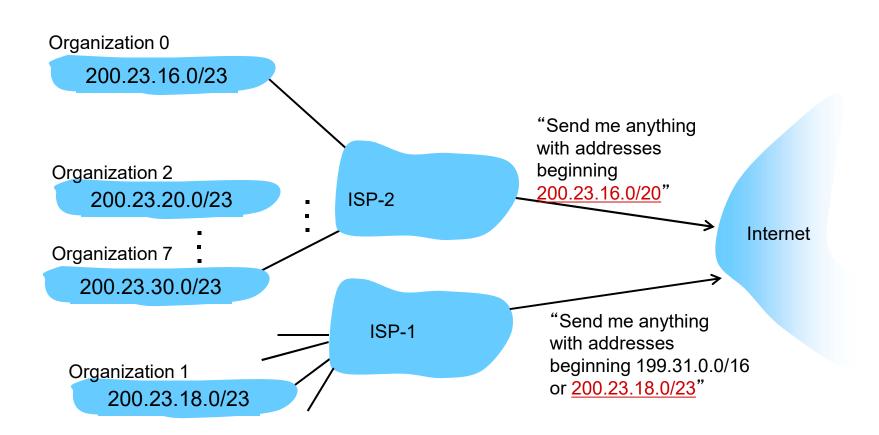

Hierarchical addressing: route aggregation

hierarchical addressing allows efficient advertisement of routing information:

Hierarchical addressing: more specific routes

ISP-I now has a more specific route to Organization I

IP addressing: the last word...

Q: how does an ISP get block of addresses?

A: ICANN: Internet Corporation for Assigned Names and Numbers http://www.icann.org/

- allocates addresses
- manages DNS
- assigns domain names, resolves disputes

What have we learned?

- IPv4 addresses 4 dotted decimal numbers 127.0.0.1
- Classless InterDomain Routing. The "slash" notation says which part of the IPv4 address is "network" and what is "host".
 - Example: 135.10.10.0/24 first 24 bits are "network" that is 135.10.10.? all on same network
- Subnetting splits a network into several subnets.
- We subnet most efficiently by picking the largest subnet first.
- DHCP (Dynamic Host Configuration Protocol) allows a host to get an IP address from the network it connects to.
